

## Features

- Programmable Charge Current Up to 1A
- Preset 4.2V charge voltage with  $\pm 1\%$  accuracy
- No MOSFET, Sense Resistor or blocking Diode Required
- Constant-Current/Constant-Voltage operation with Thermal Regulation to maximize Charge Rate Without Risk of overheating
- Charges Single Cell Li-Ion Batteries Directly from USB port
- Automatic recharge
- Battery Reverse Polarity Voltage Protection
- Charge Status Output Pin  
Two Status Indication for Charge status
- C/10 Charge Termination
- 35 $\mu$ A Supply Current in Shutdown
- 2.9V Trickle Charge Threshold
- Soft-Start Limits Inrush Current
- Monitor output charge current
- Output with protection against anti-irrigation
- Battery Temperature Sensing
- Available Package: ESOP-8
- RoHS Compliant and Lead (Pb) Free

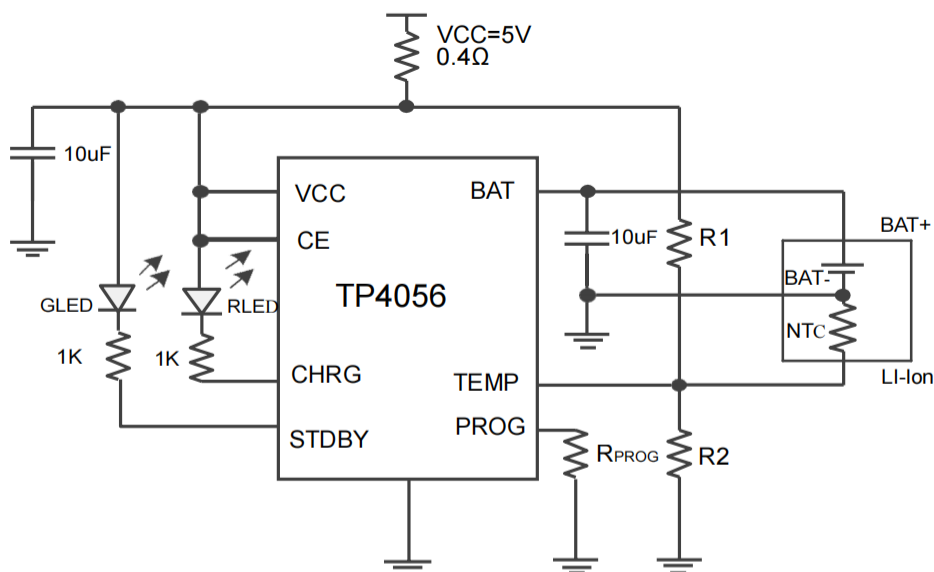

## Application

- Cellular Telephones
- Charging Docks and Cradles
- Bluetooth Application
- Wearable Application

## Description

TP4056 is a complete CC/CV linear charger for single cell lithium-ion batteries. It is specifically designed to work within USB power Specifications. No external sense resistor is needed and no blocking diode is required due to the internal P-MOSFET architecture. Thermal feedback regulates the charge current to limit the die temperature during high power operation or high ambient temperature. The charge voltage is fixed at 4.2V, and the charge current can be programmed externally with a single resistor. The TP4056 automatically terminates the charge cycle when the charge current drops to 1/10th the programmed value after the final float voltage is reached. When the input supply (wall adapter or USB supply) is removed the TP4056 automatically enters a low current state dropping the battery drain current to less than 1 $\mu$ A. The TP4056 can be put into shutdown mode reducing the supply current to 35 $\mu$ A. Other features include Battery temperature monitor, under-voltage lockout, automatic recharge and two status pins to indicate charge and charge termination

## Typical Application Circuit

## Pin Configuration (ESOP-8)

## Pin Description

Pin	Name	Function
1	TEMP	Temperature sense input
2	PROG	Constant Charge Current Setting and Charge Current Monitor Pin
3	GND	Ground
4	VCC	Positive Input Supply Voltage Pin
5	BAT	Battery connection Pin
6	STDBY	Charge terminated status output
7	CHRG	Open-Drain Charge Status Output Pin
8	CE	Chip enable input

## Order Information

Model	Marking	Description	Package	T/R Qty
TP4056		TP4056;1A;Standalone Linear Li-Ion Battery Charger; 2 Charge Status	ESOP-8	4,000 PCS

## Absolute Maximum Ratings <sup>(1) (2)</sup>

Item	Min	Max	Unit
VCC Input Voltage	-0.3	7	V
PROG PIN Voltage	-0.3	VCC+0.3	V
BAT PIN Voltage	-0.3	7	V
CHRG、TEMP、STDBY、CE PIN Voltage	-0.3	7	V
Power dissipation	Internally Limited		
Operating Junction Temperature, T <sub>J</sub>	-40	150	°C
Storage Temperature, T <sub>stg</sub>	-65	125	°C
Operating Temperature Range	-40	85	°C
Lead Temperature (Soldering, 10sec.)		260	°C

Note (1): Exceeding these ratings may damage the device.

Note (2): The device is not guaranteed to function outside of its operating conditions.

## ESD Ratings

Item	Description	Value	Unit
V(ESD-HBM)	Human Body Model (HBM) ANSI/ESDA/JEDEC JS-001-2014 Classification, Class: 2	±4000	V
V(ESD-CDM)	Charged Device Model (CDM) ANSI/ESDA/JEDEC JS-002-2014 Classification, Class: C0b	±400	V

## Recommended Operating Conditions

Item	Min	Max	Unit
Operating junction temperature <sup>(1)</sup>	-40	125	°C
Operating temperature range	-40	85	°C

Note (1): All limits specified at room temperature (T<sub>A</sub> = 25°C) unless otherwise specified. All room temperature limits are 100% production tested. All limits at temperature extremes are ensured through correlation using standard Statistical Quality Control (SQC) methods. All limits are used to calculate Average Outgoing Quality Level (AOQL).

## Thermal Information

Item	Description	Value	Unit
R <sub>θJA</sub>	Junction-to-ambient thermal resistance <sup>(1) (2)</sup>	180	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	130	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	45	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	35	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	45	°C/W

Note (1): The package thermal impedance is calculated in accordance to JESD 51-7.

Note (2): Thermal Resistances were simulated on a 4-layer, JEDEC board.

## Electrical Characteristics <sup>(Note)</sup>

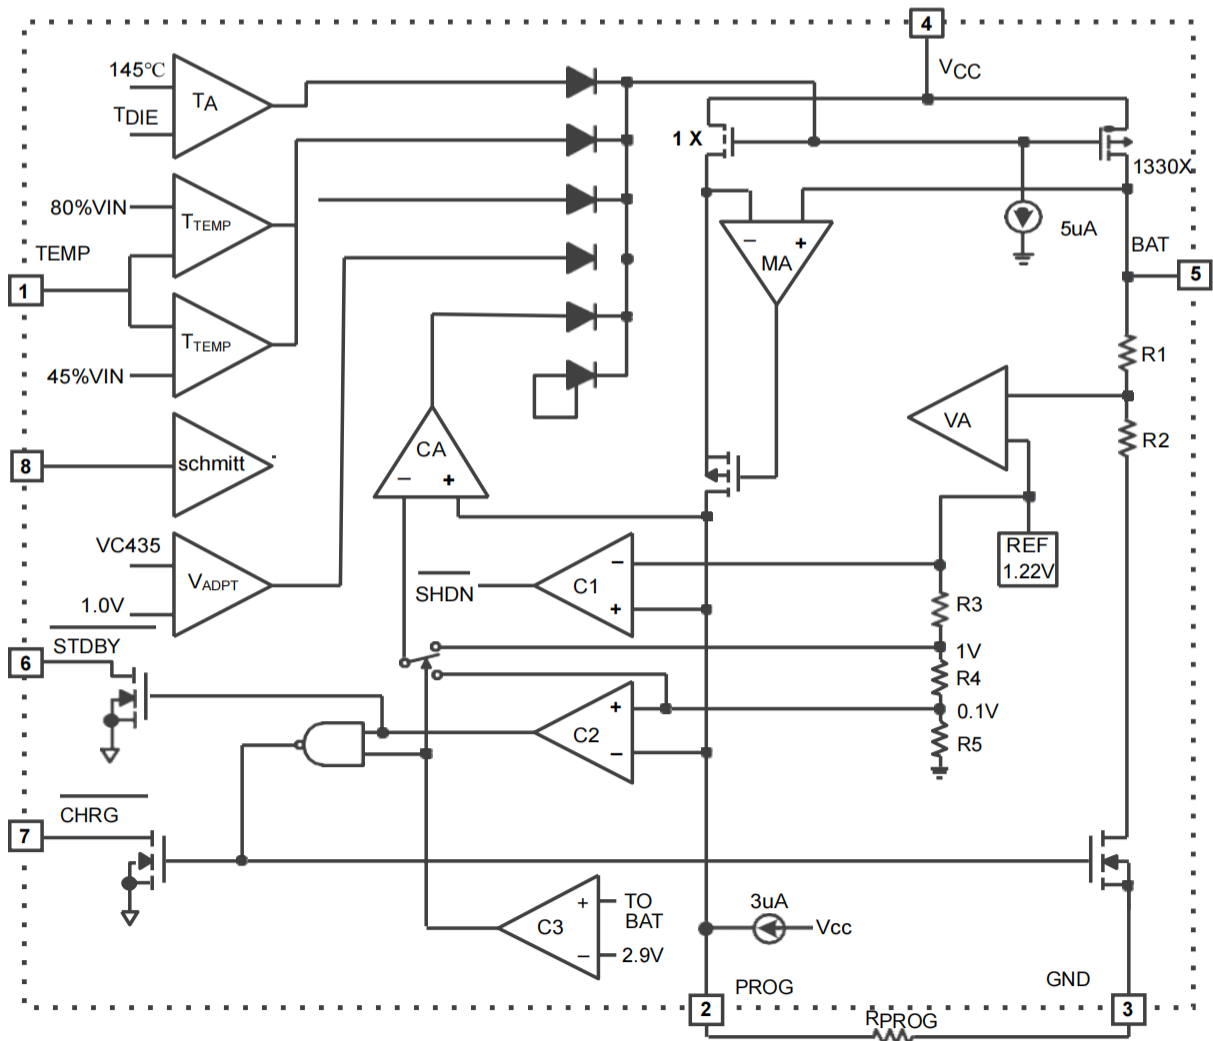

$V_{CC} = 5V$ ,  $T_A = 25^\circ C$ , unless otherwise noted.

Parameter	Symbol	Test Conditions	Min	Typ.	Max	Unit
Input Supply Voltage	$V_{CC}$		4.0	5.0	6.5	V
Input Supply Current	$I_{CC}$	Charge Mode $R_{PROG} = 1.2k$		240	500	$\mu A$
		Standby Mode (Charge Terminated)		35	100	$\mu A$
		Shutdown Mode( $R_{PROG}$ Not Connected), $V_{CC} < V_{BAT}$ , or $V_{CC} < V_{UV}$		35	100	$\mu A$
Regulated Output (Float) Voltage	$V_{FLOAT}$	$0^\circ C \leq T_A \leq 85^\circ C$ , $I_{BAT} = 40mA$	4.158	4.2	4.242	V

RechargeComparator Filter Time	t <sub>RECHARGE</sub>	V <sub>BAT</sub> High to Low	0.8	1.8	3	mS
Termination comparator Filter Time	t <sub>TERM</sub>	I <sub>BAT</sub> Falling Below I <sub>CHG</sub> /10	0.9	1.8	3	mS
Soft-Start Time	T <sub>SS</sub>	I <sub>BAT</sub> = 0 to I <sub>BAT</sub> = 1330V/R <sub>PROG</sub>		20		μS
PROG Pin Pull-Up Current	I <sub>PROG</sub>			2		μA

Note : Absolute Maximum Ratings are those values beyond which the life of the device may be impaired. The TP4056 is guaranteed to meet performance specifications from 0°C to 70°C. Specifications over the -40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls. See Thermal Considerations.

### Functional Block Diagram

## Functions Description

The TP4056 is a complete CC/CV linear charger for single cell lithium-ion batteries. CC/CV to charger batter by internal MOSFET .It can deliver up to 1A of charge current .No blocking diode or external current sense resistor is required. TP4056 include two Open-Drain charge status Pins: Charge status indicator CHRG and battery failure status output STDBY.

The internal thermal regulation circuit reduces the programmed charge current if the die temperature attempts to rise above a preset value of approximately 135°C. This feature protects the TP4056 from excessive temperature, and allows the user to push the limits of the power handling capability of a given circuit board without risk of damaging the TP4056 or the external components. Another benefit of adopting thermal regulation is that charge current can be set according to typical, not worst-case, ambient temperatures for a given application with the assurance that the charger will automatically reduce the current in worst-case conditions.

The charge cycle begins when the voltage at the VCC pin rises above the UVLO level, a current set resistor is connected from the PROG pin to ground, and the CE pin is pulled above the chip enable threshold. The CHRG pin outputs a logic low to indicate that the charge cycle is on going. At the beginning of the charge cycle, if the battery voltage is below 2.9V, the charge is in precharge mode to bring the cell voltage up to a safe level for charging. The charger goes into the fast charge CC mode once the voltage on the BAT pin rises above 2.9 V. In CC mode, the charge current is set by RPROG. When the battery approaches the regulation voltage 4.2V, the charge current begins to decrease as the TP4056 enters the CV mode. When the current drops to charge termination threshold, the charge cycle is terminated, and CHRG pin assumes a high impedance state to indicate that the charge cycle is terminated and STDBY pin is pulled low. The charge termination threshold is 10% of the current in CC mode. To restart the charge cycle, remove the input voltage and reapply it, or momentarily force CE pin to 0V. The charge cycle can also be automatically restarted if the BAT pin voltage falls below the recharge threshold. The on-chip reference voltage, error amplifier and the resistor divider provide regulation voltage with 1% accuracy which can meet the requirement of lithium-ion and lithium polymer batteries. When the input voltage is not present, or input voltage is below VBAT, the charger goes into a sleep mode, dropping battery drain current to less than 3μA. This greatly reduces the current drain on the battery and increases the standby time. The charger can be shutdown by forcing the CE pin to GND.

The charging profile is shown in the following figure:

## Programming Charge Current

The charge current is programmed using a single resistor from the PROG pin to ground. The battery charge current is 1330 times the current out of the PROG pin. The program resistor and the charge current are calculated using the following equations:

$$R_{PROG} = \frac{1250V}{I_{CHG}} \quad I_{CHG} = \frac{1250V}{R_{PROG}}$$

The charge current out of the BAT pin can be determined at any time by monitoring the PROG pin voltage using the following equation:

$$I_{BAT} = \frac{V_{PROG}}{R_{PROG}} \times 1250$$

In application, according the charge current to determine R<sub>PROG</sub>, the relation between R<sub>PROG</sub> and charge current can reference the following chart:

R <sub>PROG</sub> (K)	I <sub>BAT</sub> (mA)
12K	100
4K	300
2.4K	500
1.5K	800
1.2K	1000

## Charge Termination

A charge cycle is terminated when the charge current falls to 1/10th the programmed value after the final float voltage is reached. This condition is detected by using an internal filtered comparator to monitor the PROG pin. When the PROG pin voltage falls below 100mV for longer than t<sub>TEMP</sub> (typically 1.8mS), Charging is terminated. The charge current is latched off and the TP4056 enters standby mode, where the input supply current drops to 50µA ( Note:C/10 termination is disabled in trickle charging and thermal limiting modes). When charging, transient loads on the BAT pin can cause the PROG pin to fall below 100mV for short periods of time before the DC charge current has dropped to 1/10th the programmed value. The 1.8mS filter time

(t<sub>TEMP</sub>) on the termination comparator ensures that transient loads of this nature do not result in premature charge cycle termination. Once the average charge current drops below 1/10th the programmed value, the TP4056 terminated the charge cycle and ceases to provide any current through the BAT pin. In this state all loads on the BAT pin must be supplied by the battery.

The TP4056 constantly monitors the BAT pin voltage in standby mode. If this voltage drops below the 4.10V recharge threshold (V<sub>RECHRG</sub>), another charge cycle begins and current is once again supplied to the battery. To manually restart a charge cycle when in standby mode, the input voltage must be removed and reapplied or the charger must be shut down and restarted using the PROG pin. Figure 1 shows the state diagram of a typical charge cycle

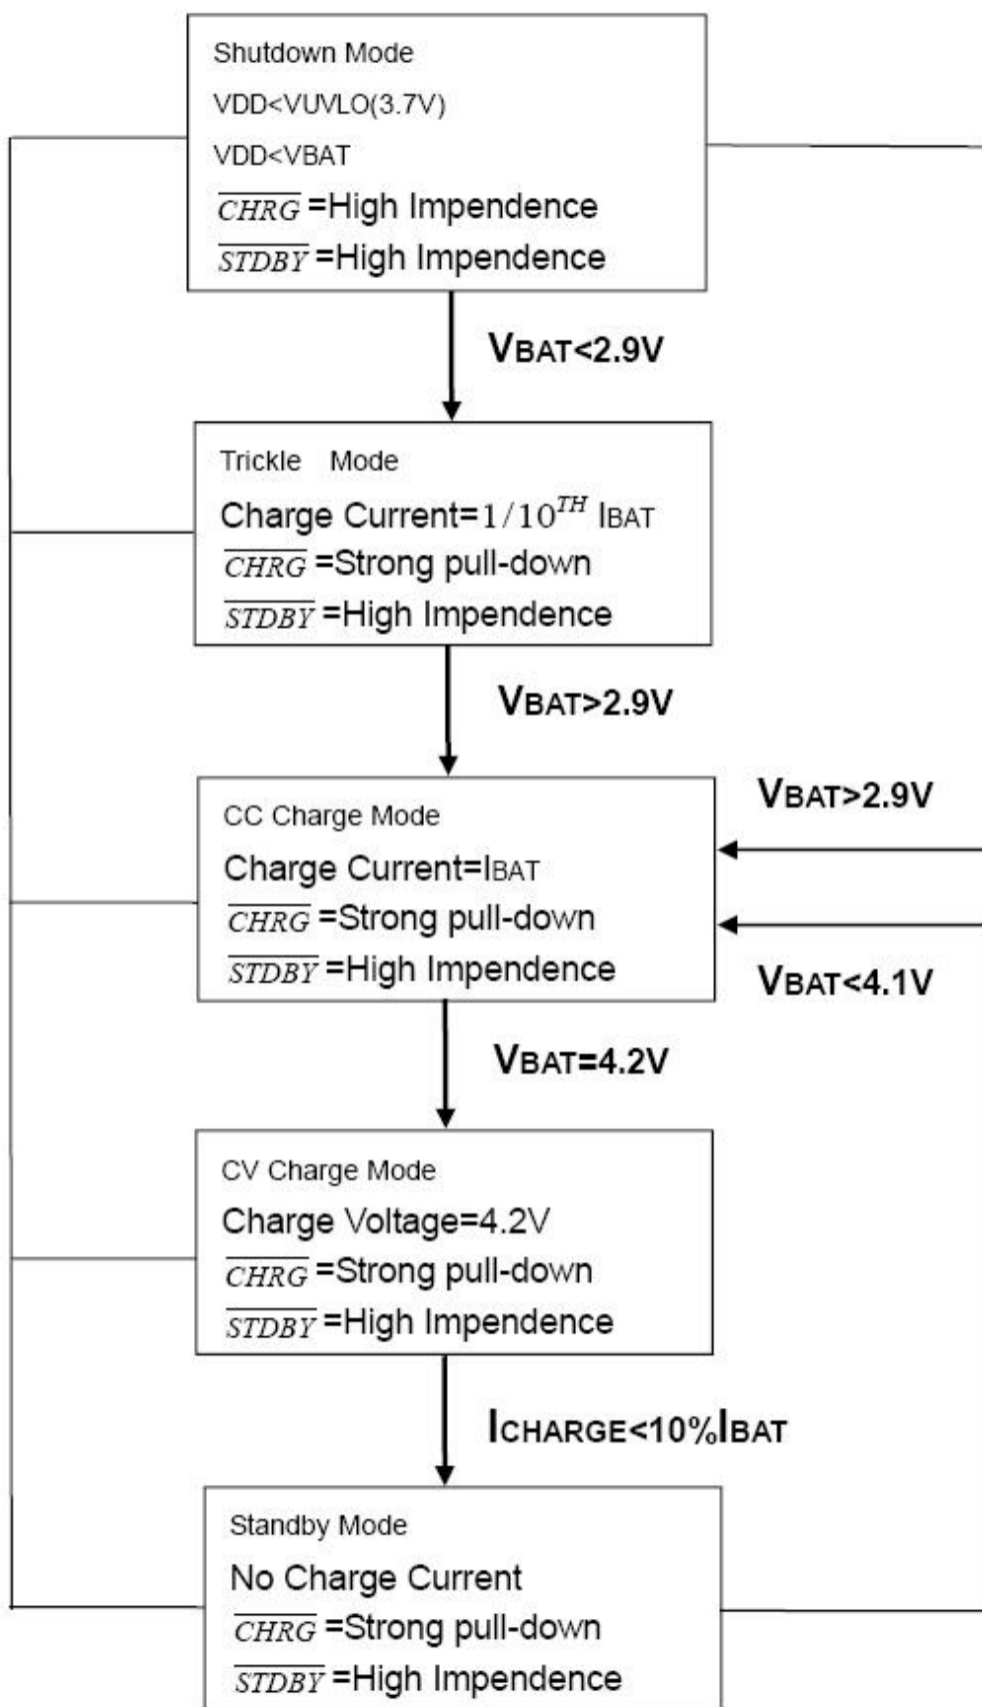

Figure :State diagram of a typical charge cycle

### Charge status indicator

TP4056 has two open-drain status indicator output CHRG and STDBY . CHRG is pull-down when the TP4056 in a charge cycle. In other status CHRG in high impedance, CHRG and STDBY are all in high impedance when the battery out of the normal temperature.

Represent in failure state, when TEMP pin in typical connecting, or the charger with no battery: red LED and green LED all don't light. The battery temperature sense function is disabled by connecting TEMP pin to GND. If battery is not connected to charger, CHRG pin outputs a PWM level to indicate no battery. If BAT pin connects a 10μF capacitor, the frequency of CHRG flicker about 1-4S, If not use status indicator should set status indicator output connected to GND.

Charger's Status	Red led CHRG	Green led STDBY
Charging	light	dark
Battery in full state	dark	light
Under-voltage, battery's temperature is too high or too low, or not connect to battery(use TEMP)	dark	dark
BAT pin is connected to 10uF capacitor, No battery mode (TEMP=GND)	Green LED bright, Red LED flicker F=1-4 S	

### Thermal limiting

An internal thermal feedback loop reduces the programmed charge current if the die temperature attempts to rise above a preset value of approximately 135℃ . The feature protects the TP4056 from excessive temperature and allows the user to push the limits of the power handling capability of a given circuit board without risk of damaging the TP4056. The charge current can be set according to typical (not worst-case) ambient temperature with the assurance that the charger will automatically reduce the current in worst-case conditions.

To prevent the damage caused by the very high or very low temperature done to the battery pack, the TP4056 continuously senses battery pack temperature by measuring the voltage at TEMP pin determined by the voltage divider circuit and the battery's internal NTC thermistor.

The TP4056 compares the voltage at TEMP pin ( $V_{TEMP}$ ) against its internal  $V_{LOW}$  and  $V_{HIGH}$  thresholds to determine if charging is allowed. In TP4056,  $V_{LOW}$  is fixed at  $(45\% \times V_{CC})$ , while  $V_{HIGH}$  is fixed at  $(80\% \times V_{CC})$ . If  $V_{TEMP} < V_{LOW}$  or  $V_{TEMP} > V_{HIGH}$ , it indicates that the battery temperature is too high or too low and the charge cycle is suspended. When  $V_{TEMP}$  is between  $V_{LOW}$  and  $V_{HIGH}$ , charge cycle resumes. The battery temperature sense function can be disabled by connecting TEMP pin to GND.

### Selecting R1 and R2

The values of R1 and R2 in the application circuit can be determined according to the assumed temperature monitor range and thermistor's values. The Follows is an example: Assume temperature monitor range is  $T_L \sim T_H$ , ( $T_L < T_H$ ); the thermistor in battery has negative temperature coefficient (NTC),  $R_{TL}$  is thermistor's resistance at  $T_L$ ,  $R_{TH}$  is the resistance at  $T_H$ , so  $R_{TL} > R_{TH}$ , then at temperature  $T_H$ , the voltage at TEMP pin is:

$$V_{TEMPH} = \frac{R_2 || R_{TH}}{R_1 + R_2 || R_{TH}} \times V_{IN}$$

At temperature TL, the voltage at TEMP pin is:

$$V_{TEMPH} = \frac{R_2 || R_{TH}}{R_1 + R_2 || R_{TH}} \times V_{IN}$$

We know  $V_{TEMPH} = V_{HIGH} = K_2 \times V_{CC}$  ( $K_2=0.8$ );  $V_{TEMPH} = V_{LOW} = K_1 \times V_{CC}$  ( $K_1=0.45$ ) Then we can have:

$$R_1 = \frac{R_{TL} R_{TH} (K_2 - K_1)}{(R_{TL} - R_{TH}) K_1 K_2} \quad R_2 = \frac{R_{TL} R_{TH} (K_2 - K_1)}{R_{TL} (K_1 - K_1 K_2) - R_{TH} (K_2 - K_1 K_2)}$$

Likewise, for positive temperature coefficient thermistor in battery, we have  $R_{TH} > R_{TL}$  and we can calculate:

$$R_1 = \frac{R_{TL} R_{TH} (K_2 - K_1)}{(R_{TH} - R_{TL}) K_1 K_2} \quad R_2 = \frac{R_{TL} R_{TH} (K_2 - K_1)}{R_{TH} (K_1 - K_1 K_2) - R_{TL} (K_2 - K_1 K_2)}$$

We can conclude that temperature monitor range is independent of power supply voltage VCC and it only depends on R1, R2, RTL and RTH: The values of RTH and RTL can be found in related battery handbook or deduced from testing data. In actual application, if only one terminal temperature is concerned (normally protecting overheating), there is no need to use R2 but R1. It becomes very simple to calculate R1 in this case.

## Under Voltage lockout (UVLO)

An internal under voltage lockout circuit monitors the input voltage and keeps the charger in shutdown mode until VCC rises above the under voltage lockout threshold. If the UVLO comparator is tripped, the charger will not come out of shutdown mode until VCC rises 140mV above the battery voltage

## Manual terminate

At any time of the cycle of charging will put the TP4056 into disable mode to pull CE pin to GND, or remove RPROG (PROG pin is float). This made the battery drain current to less than 1μA and reducing the supply current to 50μA. To restart the charge cycle, set CE pin in high level or connect a programming resistor. If TP4056 in the under voltage Lockout mode, the CHRG and STDBY are all in high impedance state, or VCC is above BAT pin 140mV, or VCC is too low.

## Auto restart

Once charge is been terminated, TP4056 immediately use a 1.8ms filter time (trecharge) on the termination comparator to constant monitor the voltage on BAT pin. If this voltage drops below the 4.1V recharge threshold (about between 80% and 90% of VCC), another charge cycle begins. This ensured the battery maintained (or approach) to a charge full status and avoid the requirement of restarting the periodic charging cycle. In the recharge cycle, CHRG pin enters a pulled down status.

## Stability Considerations

In CC mode, the PROG pin is in the feedback loop, not the battery. The CC mode stability is affected by the impedance at the PROG pin. With no additional capacitance on the PROG pin, the charger is stable with program resistor values as high as 20K. However, additional capacitance on this node reduces the

maximum allowed program resistor. Therefore, if I<sub>PROG</sub> pin is loaded with a capacitance C, the following equation should be used to calculate the maximum resistance value for R<sub>PROG</sub>:

$$R_{PROG} \leq \frac{1}{2\pi \times 10^5 \times C_{PROG}}$$

As user, may think charge current is important, not instantaneous current. For example, to run a low current mode switch power which parallel connected with battery, the average current from BAT pin usually importance to instantaneous current. In this case, In order to measure average charge current or isolate capacitive load from I<sub>PROG</sub> pin, a simple RC filter can be used on PROG pin as shown in Figure In order to ensure the stability add a 10K resistor between PROG pin and filter capacitor.

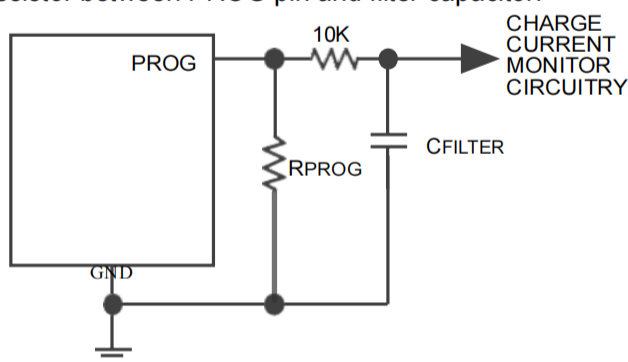

Figure : Isolating with capacitive load on PROG Pin

## Power Dissipation

The conditions that cause the TP4056 to reduce charge current through thermal feedback can be approximated by considering the power dissipated in the IC. Nearly all of this power dissipation is generated by the internal MOSFET-this is calculated to be approximately:  $PD = (V_{CC} - V_{BAT}) \times I_{BAT}$

The approximate ambient temperature at which the thermal feedback begins to protect the IC is:

$$T_A = 135^\circ\text{C} - P_D \times \theta_{JA} \quad ; \quad SO: \quad T_A = 135^\circ\text{C} - (V_{CC} \times V_{BAT}) \times I_{BAT} \times \theta_{JA}$$

For example: The TP4056 with 5V supply voltage through programmable provides full limiting current 850mA to a charge lithium-ion battery with 3.85V voltage. If J<sub>A</sub> is 100°C/W ( reference to PCB layout considerations), When TP4056 begins to decrease the charge current, the ambient temperature about:

$$T_A = 135^\circ\text{C} - (5 - 3.85) \times 0.85 \times 100 = 47.25^\circ\text{C}$$

TP4056 can work in the condition of the temperature is above 47.25°C, but the charge current will pull down to below 850mA. In a fixed ambient temperature, the charge current is calculated to be approximately :

$$I_{BAT} = \frac{145^\circ\text{C} - T_A}{(V_{VV} - V_{BAT}) \times \theta_{JA}}$$

Just as Description of the Principle part talks about so, the current on PROG pin will reduce in proportion to the reduced charge current through thermal feedback. In TP4056 design applications don't need to considerate the worst case of thermal condition, this point is importance, because if the junction temperature up to 135°C ,TP4056 will auto reduce the power dissipation.

## Thermal Considerations

Because of the small size of the thin ESOP-8 package, it is important to use a good thermal PC board layout to maximize the available charge current. The PC board copper is the heat sink. The footprint copper pads should be as wide as possible and expand out to larger copper areas to spread and dissipate the heat to the surrounding ambient. Other heat sources on the board, not related to the charger, must also be considered when designing a PC board layout because they will affect overall temperature rise and the maximum charge current.

## Add thermal regulation current

It will effective to decrease the power dissipation through reduce the voltage of both ends of the inner MOSFET. In the thermal regulation, this action of transporting current to battery will raise. One of the measure is through an external component(as a resistor or diode) to consume some power dissipation. For example: The TP4056 with 5V supply voltage through programmable provides full limiting current 1000mA to a charge lithium-ion battery with 3.8V voltage. If JA is 120°C/W, so that at 25°C ambient temperature, the charge current is calculated to be approximately :

$$I_{BAT} = \frac{135^{\circ}\text{C} - 25^{\circ}\text{C}}{(V_{CC} - I_{BAT} \times R_{CC} - V_{BAT}) \times \theta_{JA}}$$

In order to increase the thermal regulation charge current, can decrease the power dissipation of the IC through reducing the voltage (as show fig.3) of both two ends of the resistor which connecting in series with a 5V AC adapter. With square equation to calculate IBAT:

$$I_{BAT} = \frac{V_{CC} - V_{BAT} - \sqrt{(V_{CC} - V_{BAT})^2 - \frac{4R_{CC} \times (135^{\circ}\text{C} - T_A)}{\theta_{JA}}}}{2R_{CC}}$$

If  $R_{CC}=0.25\Omega$ ,  $V_{CC}=5\text{V}$ ,  $V_{BAT}=3.75\text{V}$ ,  $T_A=25^{\circ}\text{C}$  and  $J_A=120^{\circ}\text{C/W}$ , we can calculate the thermal regulation charge current:  $I_{BAT}=1000\text{mA}$ . It means that in this structure it can output 1000mA full limiting charge current at more high ambient temperature environment.

Although it can transport more energy and reduce the charge time in this application, but actually spread charge time, if TP4056 stay in under-voltage state, when  $V_{CC}$  becomes too low in voltage mode. Figure shows how the voltage reduced with increase  $R_{CC}$  value in this circuit. This technique will act the best function when in order to maintain the minimize the dimension of the components and avoid voltage decreased to minimize  $R_{CC}$ .

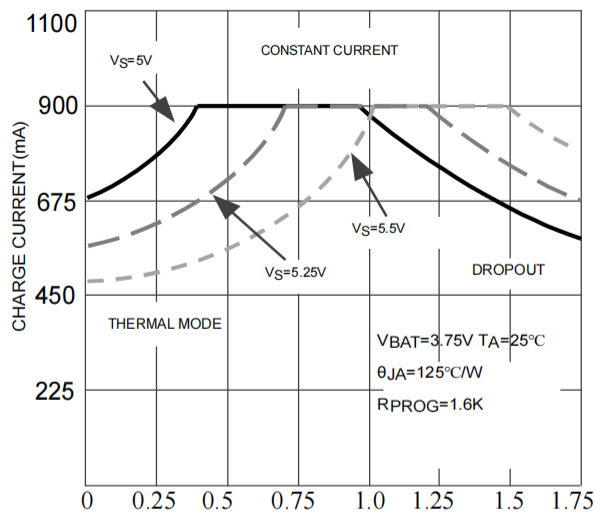

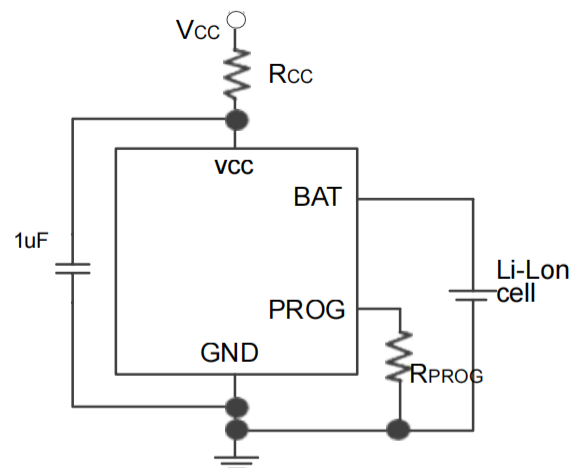

Figure: The Relationship Curve Between Charge Current With  $R_{cc}$ ; A Circuit To Maximum The Thermal Regulation Charge Current

## VCC bypass capacitor

Many types of capacitors can be used for input bypassing, however, caution must be exercised when using multilayer ceramic capacitors. Because of the self-resonant and high Q characteristics of some types of ceramic capacitors, high voltage transients can be generated under some start-up conditions, such as connecting the charger input to a live power source. Adding a  $1.5\Omega$  resistor in series with a ceramic capacitor will minimize start-up voltage transients.

## Charging Current Soft Start

TP4056 includes a soft start circuit which used to maximize to reduce the surge current in the begging of charge cycle. When restart a new charge cycle, the charging current ramps up from 0 to the full charging current within  $20\mu s$ . In the start process it can maximize to reduce the action which caused by surge current load.

## USB and Wall Adapter Power

TP4056 allows charging from a USB port, a wall adapter can also be used to charge Li-Ion/Li-polymer batteries. Figure 5 shows an example of how to combine wall adapter and USB power inputs. A P-channel MOSFET, Q1, is used to prevent back conducting into the USB port when a wall adapter is present and Schottky diode, D1, is used to prevent USB power loss through the  $1K\Omega$  pull-down resistor. Generally, AC adaptor is able to provide bigger much current than the value of specific current limiting which is 500mA for USB port. So can rise charge current to 600mA with using a N-MOSFET (Q1) and an additional set resistor value as high as 10K.

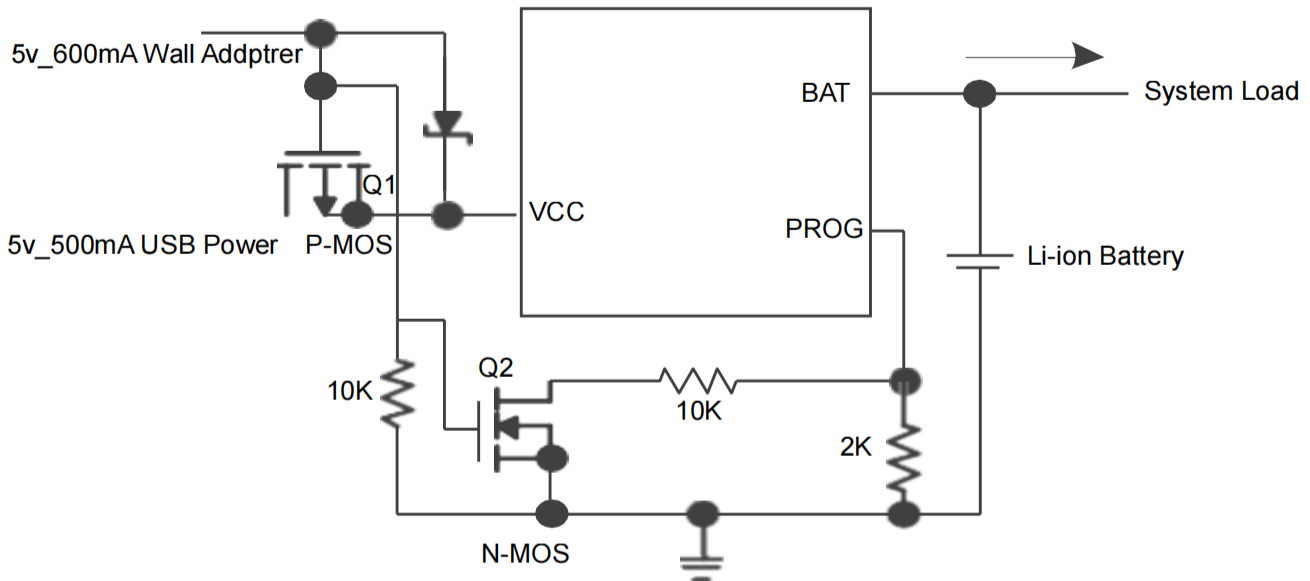

Figure:Combining Wall Adapter and USB Power

## Board Layout Considerations

$R_{PROG}$  at PROG pin should be as close to TP 4056 as possible, also the parasitic capacitance at PROG pin should be kept as small as possible. The capacitance at VCC pin and BAT pin should be as close to TP4056 as possible. During charging, TP4056's temperature may be high, the NTC thermistor should be placed far enough to TP4056 so that the thermistor can reflect the battery's temperature correctly.

It is very important to use a good thermal PC board layout to maximize charging current. The thermal path for the heat generated by the IC is from the die to the copper lead frame through the package lead (especially the ground lead) to the PC board copper, the PC board copper is the heat sink. The footprint copper pads should be as wide as possible and expand out to larger copper areas to spread and dissipate the heat to the surrounding ambient. Feed through vias to inner or backside copper layers are also useful in improving the overall thermal performance of the charger. Other heat sources on the board, not related to the charger, must also be considered when designing a PC board layout because they will affect overall temperature rise and the maximum charge current.

The ability to deliver maximum charge current under all conditions require that the exposed metal pad on the back side of the TP4056 package be soldered to the PC board ground. Failure to make the thermal contact between the exposed pad on the backside of the package and the copper board will result in larger thermal resistance.
